

SMART INDIA HACKATHON 2026

- **Problem Statement ID** –SIH26083
- **Problem Statement Title**-Extreme Heatwave Early Warning and Human Thermal Stress Index
- **Theme**-Disaster Management
- **PS Category**- Software
- **Team ID**- 161620
- **Team Name**- DataShield

Problem Overview

- India's heat warnings rely mainly on **dry-bulb temperature**, overlooking *humidity, wind, and solar radiation* that drive actual heat stress.
- IMD heat-wave** thresholds are temperature-based, not **physiological** measures of *heat stress*.
- 40°C dry vs. humid heat** can cause very different health risks.
- No system links 3–5 day **hyperlocal weather forecasts** to predicted *hospitalizations or mortality rate*.

Proposed Solution

- ThermoSafe predicts heat stress **3-5 days** ahead using **UTCI, WBGT**.
- Ward-level **mortality** and **hospitalization alert** based on *demographics, housing, and health data*.
- It includes **color** coded **GIS dashboard** to guide cooling centers, health posts, and **ambulance placement**.
- ThermoSafe pushes timely **heatwave alerts** before the danger arrives, not after.

TEMPERATURE

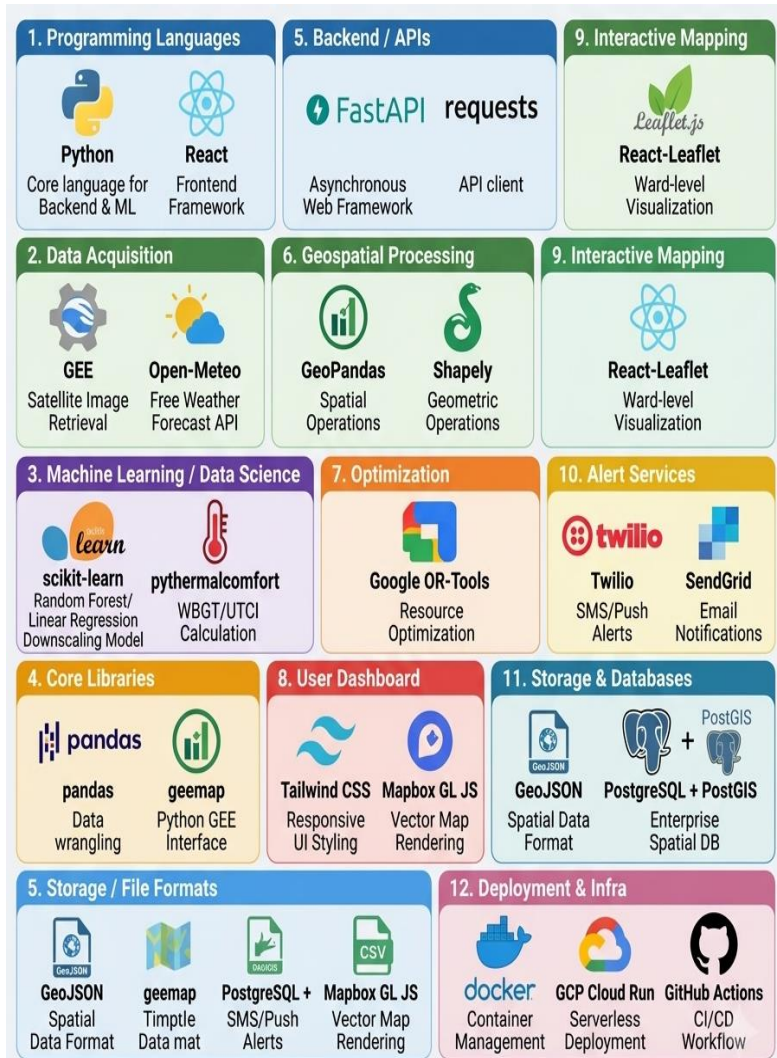

Uniqueness & Novelty

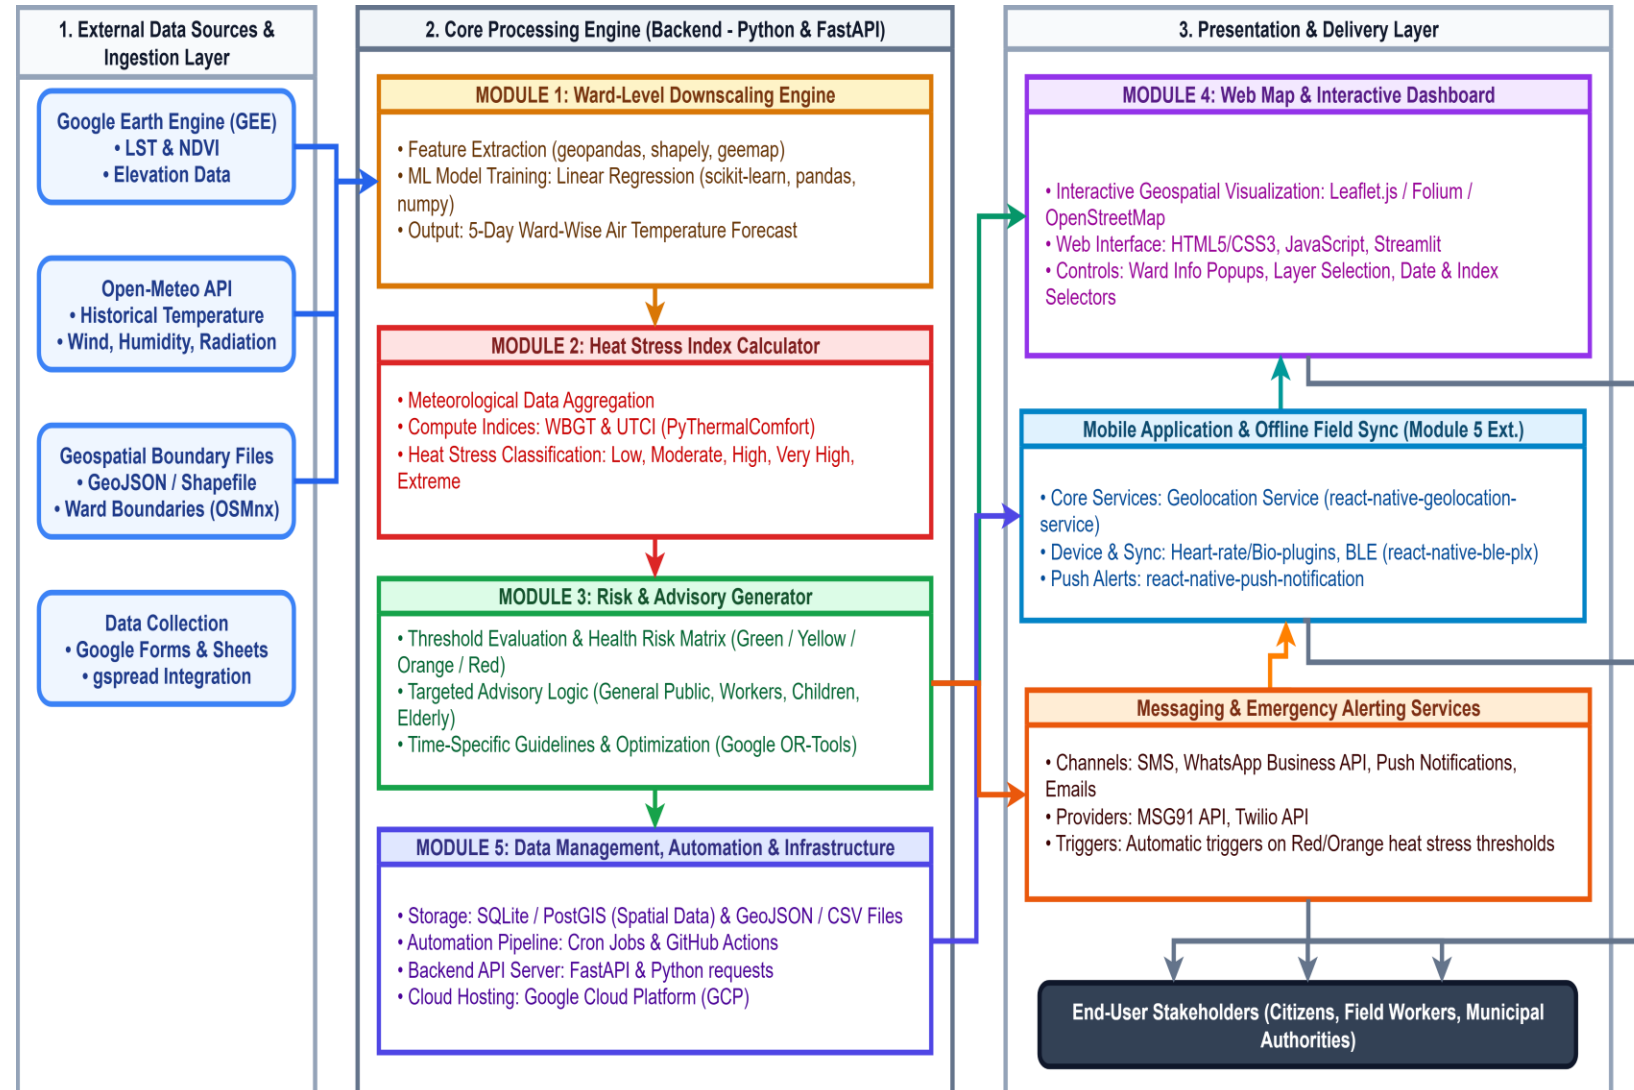

- Refined 'temperature feel'**: Additionally use vegetation or tree density (**NDVI**) and building density (**built-up%**) to measure the 'temperature feel'.
- Corrected air temp**: Uses **SUHI-to-air** scaling (unlike standard models).
- Comprehensive risk model**: Dual **mortality + hospitalization** tracking with transparent proxies.
- Ward-level insights**: Infers outdoor-worker density via OpenStreetMap where census data lacks.
- Self-calibrating thresholds**: Mortality/hospitalization cutoffs come from the city's own **historical summer data**, not another city's climate.
- Beyond Weather Apps**: ThermoSafe goes beyond coarse-grid estimates by using **ward-level satellite data on vegetation and built-up density to map heat risk** and drive targeted action.

80-89°
FATIGUE POSSIBLE WITH PROLONGED EXPOSURE / PHYSICAL ACTIVITY
90°-104°
HEAT CRAMPS, HEAT EXHAUSTION POSSIBLE
105°-129°
HEAT EXHAUSTION LIKELY, HEAT STROKE POSSIBLE
130°+
HEAT STROKE HIGHLY LIKELY

Tech Stack:

System architecture :

Feasibility of the Idea

Proven, Ready APIs

Open-Meteo, IMD, GEE & WhatsApp/SMS APIs plug in directly — no need to build from scratch.

Human-Centered Indices

UTCI & WBGT capture true physiological heat stress, not just air temperature.

Rich Public Data

Combines weather, satellite, population & vulnerability datasets.

Lean & Scalable

Open-source software & standard cloud infra GPU optional — the same pipeline expands new cities.

Mass-Reach Channels

SMS/WhatsApp alerts plus a citizen dashboard for wide accessibility.

Potential Challenges & Risks

Data & Prediction Uncertainty

Weather/satellite gaps and AI model errors can affect ward-level accuracy.

Tech & Language Barriers

Patchy internet, low smartphone access, local dialects & code-mixing limit reach.

Privacy & Govt. Integration

Consent, secure data handling, API changes & coordination delays complicate rollout.

Strategies to Overcome Them

Continuous AI Validation

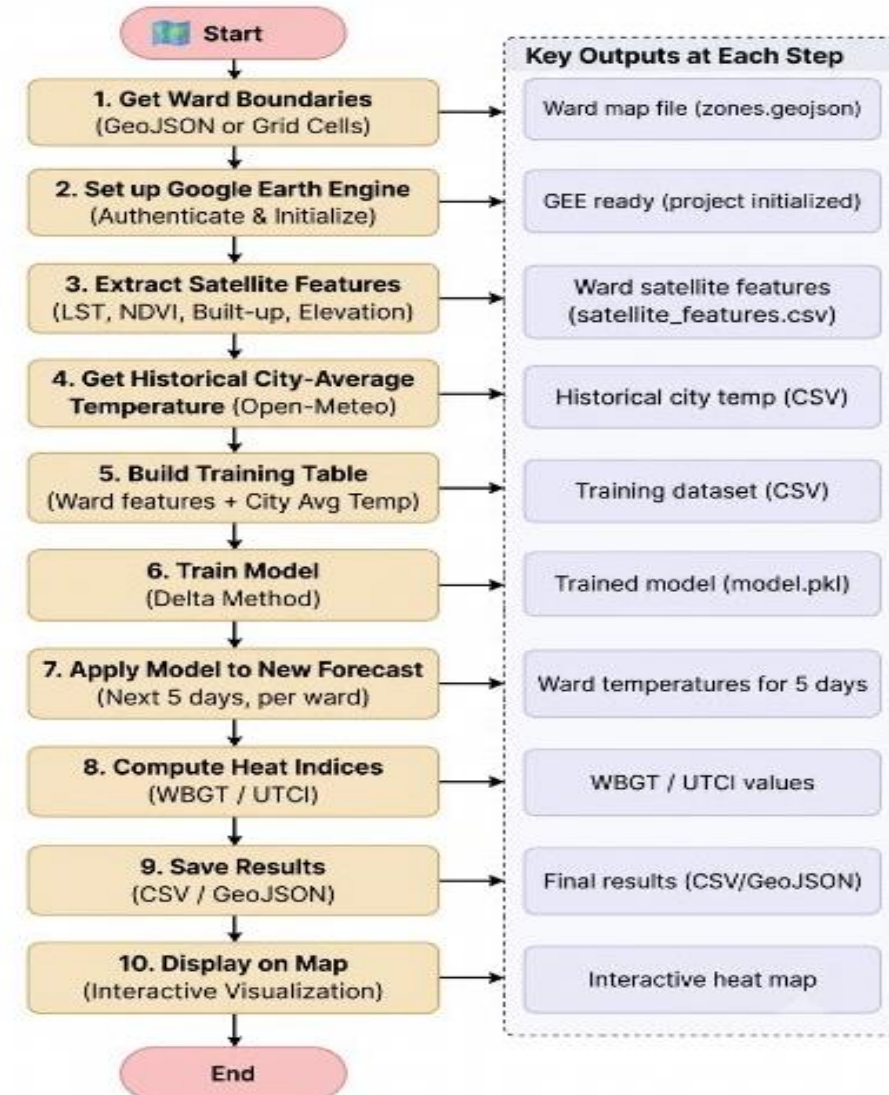

Explainable models, confidence thresholds, human-in-the-loop review & fallback alerts boost reliability.

Built for Low Connectivity

Offline/SMS support, compressed alerts, multilingual NLP & gradual local calibration close the gap.

Privacy-First Integration

Data minimization, encryption, role-based access & cached government data ensure a secure rollout.

✓ Potential impact on the target audience

Citizens

Receive hyperlocal heat-risk alerts in advance with personalized safety guidance.

Local Communities

Access timely information in local languages for better awareness and preparedness.

Hospitals

Get early alerts to prepare for a possible increase in heat-related patients.

Healthcare Teams

Improve resource and staff planning based on predicted heat-related health risks.

Authorities

Gain ward-level risk visibility for data-driven heat-action planning and timely interventions.

✓ Benefits of the solution

Hyperlocal precision over blanket warnings

Replaces city-wide forecasts with ward-by-ward risk maps so dense wards get flagged even when the official forecast looks moderate.

Lives-based prioritization, not just heat maps

Folds in elderly population, housing vulnerability & health-insurance access to show which wards need help most.

Physiologically accurate risk

Uses UTCI/WBGT (humidity, wind, radiation) instead of raw °C — critical where 'feels like' differs sharply.

Quantified, defensible impact estimates

Outputs expected excess deaths per ward using peer-reviewed dose-response relationships for concrete planning.

Built on free, open & scalable infrastructure

Google Earth Engine, Open-Meteo, WorldPop & NFHS-5 — zero licensing cost, easily replicated across Indian cities.

Urban Vulnerability, Micro-Climate & Downscaling
